

1

P2V converts from a physical address to a virtual address in the kernel's memory. The xv6 kernel makes sure that every page table maps (for the kernel's use only) virtual address  $0x80000000+x$  to physical address  $x$ , and P2V uses these addresses (that is, it adds  $0x80000000$ ). V2P does the opposite mapping.
